

B Dataverse Appendix

Classifying law enforcement candidates and candidates' professional backgrounds

I classify council candidates as law enforcement candidates if their ballot names have one of the following terms (including gender and spelling variations, and abbreviations): soldado, cabo, sargento, tenente, major, coronel, general, comandante, delegado, capitão, policial, civil, investigador, inspetor, sub-tenente, pm, xerife. Some police officers, mainly *delegados*, are commonly given a title of “*doutor*.” For this reason, I classify as law enforcement candidates those candidates who put *doutor* in their ballot name, and at the same time declare their occupation as a police officer.

Candidates' occupation information comes from their self-reported answers to the electoral authority's questionnaire prior to every election. I classify a candidate's professional background as a police officer if the occupation she listed is polícia civil, polícia militar, or delegado de polícia. Armed forces candidates are militar em geral, militar reformado, oficiais das forças armadas e forças auxiliares, membro das forças armadas.

When analyzing candidates' occupations it is possible to identify some candidates who were in fact law-and-order candidates, but who either due to typographical errors (sargente instead of sargento was a recurring one) or due to very short abbreviations (for example sd to designate soldado) had not been detected using regex. These were added manually and made up 6% of all hits.

The social media analysis further validates the use of ballot names to classify law-and-order candidates. In total, 64% of candidates who used ballot names had aliases with law-and-order signaling – even in accounts created before they became politicians. Law enforcement professionals without law-and-order ballot names used law-and-order monikers only 4.7% of the time.

B.1 Graphical representation of discontinuity: Balance tests and different polynomials

Figure B.1: Balance tests – municipal-level covariates (and difference in homicides)

Figure B.2: Balance tests – individual level covariates

Figure B.3: Discontinuity Plots for Homicide Rates

Graphical representation of the discontinuity and alternative specifications

The figures below show alternate discontinuity plots using different polynomials. They all indicate that the linear models that are presented in the main text are the most conservative. Results are considerably larger in higher-degree polynomials.

B.2 Social media variables

I sampled candidates by the following steps:

1. Select list of 2020 **elected** law-and-order candidates and list of **elected** candidates with a law enforcement occupation (self-reported)
2. (for analysis of police connections) For each list, order candidates alphabetically and extract candidates who listed *Polícia Militar* as their occupation.
3. Bind a vector of random numbers to each group of candidates.
4. Re-order lists in increasing order of random numbers.
5. Make two lists containing the top 80 candidates in each group.
6. For each entry, search for Instagram account. If found, proceed to code variables.
7. Failing to find Instagram account, search for Facebook account. If found, proceed to code variables.
8. If social media is not found, search for social media information in Municipal Council website. If found, proceed to code variables.
9. If social media is not found, report that candidate did not have a social media account

Coding the variables:

1. `Ballot name`: Does the candidate's social media address include a law-and-order name?
2. `Post with police`: Is there a picture of the candidate with patrolling police officers? A picture with a police chief is also a picture with a police officer.
3. `Post with police chief`: Is there a picture of the candidate with a police chief (captain, lieutenant, colonel)? Pictures honoring police chiefs without the candidate together do not count. Old pictures (before the term begins) do not count.
4. `credit claiming`: Is there an attempt at credit claiming for public security in any post? Credit-claiming instances are candidates' initiatives towards public security or any initiative that the candidate claims to be an effort to improve public security. These can be resources for police; cameras in public places; efforts to secure funding for public security with the mayor, and subnational or national politicians.

All coding was performed in February 2022. The examples used in the main text are retrievable at these addresses:

- CCTV systems: <https://archive.ph/WOZBK>
- Increased the ranks of local police: <https://archive.ph/anAKL>
- Protested for better wages and conditions for police officers: <https://archive.ph/js0ME>

B.3 Effect on crime

The Ministry of Justice provides municipal crime data through the National System of Public Security Statistics and Criminal Justice (SINESPJC).⁴⁵ The ministry aggregates all crime data from different state police authorities. The dataset contains crime statistics for four large groups of crimes: car thefts, car robberies, sexual assaults, and robbery homicides. Data for all municipalities is available starting in 2012, and for this reason, the dependent variable for crime is not the difference but levels. In addition, the available data make estimations for subgroups of law-and-order candidates low-powered.

Estimates for crime are not precise, but crime rates appear to decrease after the election of police law-and-order candidates. Since crime data is not available for all years, much less for all municipalities, estimations do not have the same statistical power as other tests.
